1. Introduction

Since the syntheses of Ln-1) (Ln = lanthanide metals), Mg-2) and Zr-based3–5) bulk glassy alloys, a number of bulk glassy alloys have been developed in multi-component systems during the last decade.6–8) Especially the Zr- and Pd–Cu-based bulk glassy alloys have been used as practical materials of sporting goods and electrodes6–8) Considering applications as engineering materials, development of bulk glassy Ni-based alloys is of great importance and high chemical stability in severe environment can be expected for Ni-based glassy alloys. Although a number of Ni-based amorphous alloys have been prepared by melt spinning, the formation of bulk glassy Ni-based alloys was reported only in recent years, as exemplified for Ni–Nb–Cr–Mo–P–B,9) Ni–Co–Fe–Cr–Mo–Nb–P–B,10) Ni–Cr–(Mo, Ta)–P–B,11) Ni–Nb–Ta–P12) and Ni–Cr–Ta–Mo–P–B13) systems, which exhibited high corrosion resistance in corrosive acids. However, the addition of P is disadvantageous because of its high vapor pressure during preparation of master alloys. Subsequently, formation of bulk glassy alloys in Ni–Ti–Zr–(Si, Sn) system has been reported, but there are no data on their chemical properties.14) Furthermore, it is known that the existence of metalloid elements in their alloys is detrimental for mechanical properties, such as ductility.

Recently, new Ni-based bulk glassy alloys free from metalloids with high strength and good ductility have been synthesized for the first time in Ni–Nb–Ti–Zr base system by melt-cast or copper-mold casting method.15) It is well known that valve metals, such as Nb, Ti and Zr, are corrosion-resistant elements in aggressive acids with low oxidizing ability. It is also considered that Co and Ni are ferrous group elements located next to each other in the periodic table and their atomic sizes are small.16) Therefore, we have systematically explored Ni60−xCo0.5,125,18.5,30,35,40) alloys with regards to the effects of substituting Ni with Co on the glass-forming ability and corrosion behavior. This paper presents the composition range in which glassy alloys with a large supercooled liquid region before crystallization are formed in the Ni–(Co–)Nb–Ti–Zr system. The formation, thermal properties and corrosion behavior of their bulk glassy alloys are investigated.

2. Experimental Procedure

Alloy ingots with nominal compositions of Ni60−xCo0.5,Nb20,Ti10,Zr10 (x = 0, 5, 10, 15, 20, 30, 40 and 50 at%) were prepared by arc melting mixtures of the pure metals in an argon atmosphere. From the master alloys, ribbon samples with a cross section of 0.02 x 1 mm2 were fabricated by melt spinning. Bulk alloys in a rod form with a length of about 40 mm and diameters up to 2 mm were prepared by copper-mold casting. The structure of the specimens was examined by X-ray diffraction (XRD) using Cu–Kα radiation. The thermal stability associated with glass transition, supercooled liquid and crystallization for the glassy alloys was investigated by differential scanning calorimetry (DSC) at a heating rate of 0.67 K/s. Corrosion behavior of the bulk glassy alloys was evaluated by potentiodynamic polarization with a potential sweep rate of 10−3 A/m2 and no pitting corrosion due to anodic polarization with a potential sweeping up to 2.0 V vs. Ag/AgCl occurred, indicating their high corrosion resistance in the aggressive acid.

Figure 1 shows the DSC curves of the melt-spun Ni60−xCo0.5,Nb20,Ti10,Zr10 (x = 0, 5, 10, 15, 20, 30 and 40 at%) alloys, there was a main halo peak at diffraction angles (2θ) of around 42 degrees in their XRD patterns and no diffraction peak corresponding to a crystalline state was seen. However, the XRD pattern of the alloy containing 50 at%Co exhibited crystalline peaks. It is indicated that the Ni60−xCo0.5,Nb20,Ti10,Zr10 alloys containing 0–40 at%Co can be formed in a glassy single-phase state without crystallinity by melt spinning.

Keywords: bulk glassy alloy, nickel-based alloy, supercooled liquid region, corrosion

(Received April 17, 2002; Accepted May 20, 2002)
alloys, where \( T_g \) and \( T_x \) correspond to glass transition temperature and onset temperature of crystallization, respectively. The distinct glass transition, followed by a supercooled liquid region prior to crystallization, is recognized for the alloys containing 0–30 at%Co, though no glass transition is seen for the 40 at%Co alloy. A large temperature interval of supercooled liquid region (\( \Delta T_x \)) of about 50 K, defined by the difference between \( T_x \) and \( T_g \) (\( \Delta T_x = T_x - T_g \)), is recognized for the glassy Ni\(_{60-x}\)Co\(_x\)Nb\(_{20}\)Ti\(_{10}\)Zr\(_{10}\) (\( x = 0, 5, 10 \) and 15 at%) alloys, indicating a high thermal stability of the supercooled liquid. For the alloys containing 20 and 30 at%Co, the \( \Delta T_x \) decreases to 40 K and 32 K, respectively, due to a slight increase in \( T_g \) and a distinct decrease in \( T_x \).

Furthermore, bulk alloys with diameters of 1–1.5 mm consisting of a glassy single phase were formed in the composition range of 0–20 at%Co for the Ni\(_{60-x}\)Co\(_x\)Nb\(_{20}\)Ti\(_{10}\)Zr\(_{10}\) alloys. Their outer surfaces were smooth and no concave due to the precipitation of a crystalline phase was seen. Figure 2 shows the X-ray diffraction patterns of the bulk glassy alloys with their maximum diameters for glass formation. It is seen that the maximum diameter for glass formation is 1 mm for the 0, 15 and 20 at%Co alloy. With the addition of 5 and 10 at%Co for replacing Ni, the glass-forming ability of the alloys is increased as evidenced from the formation of bulk glassy rods with diameters up to 1.5 mm. The glassy single-phase nature of the bulk samples was further confirmed by comparing their DSC curves with those of the melt-spun ribbons. Figure 3 shows the DSC curves of the glassy Ni\(_{55}\)Co\(_{2}\)Nb\(_{20}\)Ti\(_{10}\)Zr\(_{10}\) melt-spun ribbon and cast rods with diameters of 1 mm and 1.5 mm. The heat of the main exothermic peaks is 3.9 kJ/mol for the 1 mm rod, 4.2 kJ/mol for the 1.5 mm rod and 4.0 kJ/mol for the melt-spun ribbon. It is indicated that there is no distinct difference in the \( T_g, T_x \) and heat of the crystallization reactions among the bulk and ribbon samples.

As described above, the glassy Ni\(_{60-x}\)Co\(_x\)Nb\(_{20}\)Ti\(_{10}\)Zr\(_{10}\) (\( x = 0–20 \) at%) alloys exhibited a high thermal stability of supercooled liquid against crystallization (\( \Delta T_x \geq 40 \) K) and high glass-forming ability leading to the formation of the bulk glassy rods with diameters up to 1.5 mm. By contrast, the melt-spun 30 at%Co alloy exhibited a small \( \Delta T_x \) value of 32 K and the 40 at%Co ribbon showed no glass transition and no bulk glassy samples were obtained by using these two alloy compositions. It has been proposed that the alloys possessing high thermal stability of supercooled liquid against crystallization satisfy the three composition rules for the achievement of high glass-forming ability,\(^6,7,17\) i.e., (1) multi-component system consisting of more than three elements, (2) significant difference in atomic size ratios above about 12% among the main constituent elements, and (3) suitable negative heats of mixing among their elements. The atomic size changes in the order of Zr \( \gg \) Nb \( \gg \) Ti \( \approx \) Co = Ni\(^{16}\) and the heat of mixing is negative values of 25–49 kJ/mol for the atomic pairs of (Ni, Co)–Nb, (Ni, Co)–Ti and (Ni, Co)–Zr\(^{18}\). Thus, the data on the atomic size and the chemical bonding nature of the Ni–(Co–)Nb–Ti–Zr system indicate the satisfaction of the three composition rules,
Formation of Bulk Glassy Ni–(Co–)Nb–Ti–Zr Alloys with High Corrosion Resistance

leading to the formation of the bulk glasses with a large supercooled liquid region. The mechanism for the stabilization of supercooled liquid for the alloys satisfying the composition rules has been described in previous papers and reviews.6, 7, 17)

The bulk glassy Ni$_{60-x}$Co$_x$Nb$_{20}$Ti$_{10}$Zr$_{10}$ alloys containing 0–20 at%Co exhibited nearly the same polarization behavior in 1 N HCl solution. As examples, the anodic polarization curves of the bulk glassy alloys containing 0, 5 and 20 at%Co measured potentiodynamically are shown in Fig. 4. All the glassy alloys exhibit high open-circuit potential of above 0 V vs. Ag/AgCl. In the corrosive hydrochloric acid, they are spontaneously passivated and showed a low passive current density of the order of $10^{-2}$ A/m$^2$ until the evolution of O$_2$ and/or Cl$_2$ gases starts at the potential of about 1.35 V vs. Ag/AgCl. No pitting due to the polarization with a potential up to 2.0 V vs. Ag/AgCl occurred. These results indicate high corrosion resistance of the glassy Ni$_{60-x}$Co$_x$Nb$_{20}$Ti$_{10}$Zr$_{10}$ alloys in the aggressive HCl solution. The high corrosion resistance of the glassy Ni–(Co–)Nb–Ti–Zr alloys is primarily attributed to the formation of a single solid solution alloy exceeding the solubility of alloying elements in the equilibrium state and hence allowing selective alloying of strongly passivating elements, Nb, Ti and Zr, which ensure the formation of a uniform and highly protective passive film.

4. Summary

Formation of glassy alloys in Ni–Co–Nb–Ti–Zr system with high thermal stability and corrosion resistance is reported. A glassy single phase was formed for Ni$_{60-x}$Co$_x$Nb$_{20}$Ti$_{10}$Zr$_{10}$ ($x = 0–40$ at%) alloys by melt spinning. The glassy alloys exhibited a large $\Delta T_x$ of about 50 K in the composition range of 0–15 at%Co and 40 K at 20 at%Co. Bulk glassy alloys with a diameter up to 1.5 mm were synthesized by using the 0–20 at%Co alloys with the large $\Delta T_x$. There was no distinct difference in polarization behavior for the bulk glassy alloys containing 0–20 at%Co in 1 N HCl solution. They were spontaneously passivated at a low current density of the order of $10^{-2}$ A/m$^2$ and no pitting corrosion due to anodic polarization with a potential sweeping up to 2.0 V vs. Ag/AgCl occurred in 1 N HCl solution.
